Most current commercially available and in particular ink jet technology are electrostatic printers. This technology includes the use of both continuous and drop-on-demand drop generation technologies. For example, continuous ink jet technology, as exemplified by Kyser et al in U.S. Pat. No. 4,463,359 and short-throw drop-on-demand technology, as exemplified by Yeatman et al in U.S. Pat. No. 5,281,826. The print heads of the above electrostatic printers generally contain replaceable ink cartridges which are connected to an electrical supply and include a series of nozzles to spray ink. The print head is mounted on a carriage which is reciprocated to produce the images from the cartridges. The ink contained in the cartridges is usually dispensed onto specially treated paper through a post or an array of nozzles. Conventionally, the cartridges include two major components, the ink tank and the print head. The print head includes a layer of polymeric material which contains a series of nozzles. The nozzles are either formed by etching the layer or printed on the polymeric layer, which has been primed with a suitable material. The ink is held in the ink tank and forced to the no

What's New In?

The invention relates generally to wellbore penetrating devices and more particularly to a collapsible coil forming unit adapted to be run into a wellbore from a landing position to an operating position, whereupon it is capable of securing a downhole tool in the wellbore. Collapsible coil tubulars are well known in the prior art and disclosed in such references as U.S. Pat. Nos. 5,085,918, 5,145,099 and 5,339,898, which teach the use of a series of concentrically disposed, axially movable coils to form a spiral spring to retain a downhole tool and U.S. Pat. Nos. 5,301,891 and 5,307,767 teach an adjustable length coil spring. The prior art coil forming devices operate on the principle of driving the ends of the coil tubular downwardly to coil the spring about itself. In the case of the axially movable coil spring device, there is a substantial reliance on hydraulic power for moving the coil spring. In the case of the fixed diameter coil spring, the spring at one end is moved downwardly into contact with the bottom of the wellbore. The power required to cause the end of the spring to grip the bottom of the wellbore is substantial, and undesirably high mechanical power must be provided to the fishing string or to a cable connected to the fishing string to raise the coil spring forming device to cause the coil to slide past a hydraulic release mechanism located at the top of the wellbore. There is a continuing need for a coil forming device which is capable of deploying and retrieving downhole tools without relying upon hydraulic power which is undesirably limited and subject to the pumping down of a drilling or production string from the surface. The invention provides a coil spring forming device adapted to be retrieved to the surface of the wellbore without the need for hydraulic power or the need for setting a mechanical release mechanism. After retrieval, the spring forming device is lowered into the wellbore and the coil spring is extended about itself by moving the device downwardly so that the coil spring forms a series of springs which extend in a spiral along the length of the wellbore. Each spring will exert a radial force on the inner wall of the wellbore, as well as provide a radial pressure on the downhole tool attached to the end of the coil spring. A first major advantage of the present invention is that the coil forming
